FIRST AID FOR THE OUTDOORS
Teaching Outline
Keith Conover, M.D., FACEP
Version 3.1   April 21, 2012

Motivate:
In most outdoor rescue situations, you initially have little to work with: no or few bandages and splints, no IV's, no oxygen, no hotpacks. You DO have your mind and your hands and senses, which are invaluable medical and first aid tools. The purpose of this half-hour of lecture and 45 minutes of practice is to show you how to use minimal equipment for initial management of the injured person. The American Heart Association touts the “Universal Algorithm” for CPR and ACLS -- however it needs to be expanded to include other problems to be a truly “Universal Algorithm” and this is it.

I. FIRST AID

A. STEP ZERO: ASSESS AND MANAGE HAZARDS. “The first principle in management of the injured person: take care of HAZARDS. Start first aid only after ensuring safety (the victim’s AND yours) from hazards, such as falling, rockfall, severe cold exposure, or flooding.” (“A dead rescuer never did anyone any good.”) Cold and wet can be hazards, too; moving the patient to prevent heat loss may be a high priority. Need to insulate under as well as over.

B. STEP 1: PRIMARY SURVEY. Do a PRIMARY SURVEY, looking for life-threatening conditions; correct them as you find them. There are only a few absolute rules in first aid, but one of them is: always check airway, breathing, and circulation, in that order. Newer CPR algorithms emphasize circulation first, but for most backcountry situation, the old ABC still makes more sense. Of course, if you ask a victim ‘Are you alright?’ and get a ‘No, dammit, I think I’ve broken my ankle’ then you can guess that airway and breathing are OK.

1. STEP A: AIRWAY.
   a. STEP A-1: CHECK FOR AIR MOVEMENT. Tell students that if patient is NOT talking, to look, listen, feel for air movement.
   b. STEP A-2: OPEN AIRWAY. If none, initiate neck hyperextension or jaw thrust (demonstrate). Tell students to take a CPR course to learn care of the obstructed airway.
   c. Mention need for maintaining neck in neutral position if suspicion of neck injury, e.g. after a fall; demonstrate use of jaw thrust/neck stabilization.
   d. Explain that care of airway is important after primary survey as well: use coma/recovery position (left lateral decubitus) to protect airway and lungs of unconscious person (explain why: danger of aspiration of secretions or vomit); stabilize neck if necessary. Explain the use of padding to support head.

2. STEP B: BREATHING.
   a. STEP B-1: ARTIFICIAL RESPIRATION. Tell students to take a CPR course to learn artificial respiration.
   b. STEP B-2: PLUG SUCKING CHEST WOUND. Explain what a sucking chest wound is, and that it should be plugged up with whatever is handy. Someone will ask ‘What if a tension pneumothorax develops?’ Answer: unplug it for a minute, then plug it up again.
   c. STEP B-3: SPLINT MAJOR FLAIL CHEST. Explain what a flail chest is, and how to stabilize it with a cave pack or other splint; and, that stabilizing it with the one lung collapsed will decrease the work of breathing and decrease bleeding and pain.

3. STEP C: CIRCULATION.
   a. STEP C-1: CARDIAC RESUSCITATION. Check pulse; tell students to take a CPR course to learn external cardiac compression. Note that you shouldn’t do cardiac compression in the backcountry if exhausting yourself. Note that you shouldn’t do cardiac compression in the backcountry if (1) traumatic arrest, (2) exhausting yourself puts you in danger; and, regardless, give up after half an hour.
b. **STEP C-2: CONTROL SEVERE BLEEDING.** Check for **SEVERE** bleeding: use direct pressure and elevation to stop it. Explain that tourniquet may be used temporarily, and that tourniquets must be wide and tight. Explain that pressure points are rarely useful.

c. **STEP C-3: DETECT AND TREAT SEVERE SHOCK.** Check pulse for life-threatening shock:
   i. weak, thready rapid pulse in an anxious, thirsty victim = shock.
   ii. treat: elevate legs, keep warm, reassure, consider oral fluids. (Backcountry rule: do not starve or dehydrate people unless you’re absolutely sure it’s the right thing to do.)

C. **STEP 2: MANAGE.** “Stand back – Look – Think – MANAGE! Once the immediately life-threatening situations are under control, hold back and figure out what else needs to be done. If you get too deeply involved in first aid, you may lose track of other things that need to be done: (e.g. waiting 2 hours to send someone for help – it’s happened!) Partition up the work to be done; find something for everyone to do.”
   (“Don’t just do something, stand there!”)

D. **STEP 3: FOCUSED H & P.** Do a **FOCUSED H & P** for additional injuries. Start at head and work down, feeling for deformity or tenderness, looking for bruising or other injury.

1. **HEAD/NEUROLOGICAL EXAM**
   a. The major problem with a head injury is that pressure from bleeding or bruising can build up inside the skull, ‘squishing’ parts of the brain; there are 3 main ways of telling whether or not this is happening:
      When the brain is being squished more and more, the **LEVEL OF CONSCIOUSNESS**
      goes down: the person becomes more and more lethargic, and less responsive to voice or pain.
   
   ii. When the nerve to the eye is being compressed, it may cause one of the pupils to respond to light less well, and may end up completely dilated (a big, black pupil that does not respond to light.) This only occurs in badly head-injured patients; and 10% of the population have unequal pupils.
   
   iii. Pressure on certain parts of the brain may cause weakness or numbness of certain parts of the face or body, or even seizures starting in certain parts of the body. Check for progression (worsening symptoms in more areas)

   b. There’s little that can be done in the field for a head injury; poor breathing can make it worse, and mild hyperventilation is sometimes used to help; keeping the head level or slightly higher than the feet is also a good idea. Avoid any pressure on the neck (very important).

   c. If there is a decreasing level of consciousness, possibly coupled with a ‘blown’ pupil, paralysis, or seizures, then the pressure inside the skull is increasing and the person must be evacuated to a hospital NOW or he will probably die. Ask for a helicopter.

2. **NECK**
   a. check sensation, movement (response to and movement from pain if unconscious) in all extremities; if OK, means probably no damage to spinal cord, BUT in unconscious patients, bony spine may still have fractures that may sever cord on movement.

   b. feel the spine for deformity, tenderness (note that C7 has a prominent spine, which is normal)

   c. If fully alert, awake, not intoxicated, no neurological symptoms, no distracting injury, and no neck pain or neck tenderness in the midline, don’t need to worry about cervical spine injury. (Discuss NEXUS rule.)

   d. **The general principle is NOT** to move a stable person with a suspected spine injury until a properly-designed backboard is available; however, if the person has some other problem that needs URGENT treatment (severe shock, decreasing level of consciousness), then you must use improvised spinal immobilization.
3. CHEST
   a. (Sucking chest wounds and flail chest were discussed under Primary Survey.)
   b. Explain: collarbones are splinted by splinting the arm to the body; fractured ribs don’t need to be splinted unless flail chest is present.

4. ABDOMEN AND PELVIS
   a. Explain and demonstrate evaluation of the abdomen:
      i. LOOK for wounds, bruising, or distension;
      ii. LISTEN for bowel sounds (absence is relatively bad).
      iii. FEEL for guarding (involuntary rigidity of muscles)
   b. Explain that internal bleeding alone may cause shock; cannot control bleeding, but can treat early for shock.
   c. Explain and demonstrate examination of the bony pelvis (press on symphysis, in on iliac crests, and out on iliac crests); pain or abnormal motion indicates a fracture – fracture may cause death due to internal blood loss.

5. EXTREMITIES
   a. Principles of splinting:
      1. Long bone fractures: immobilize the joint above and joint below.
      2. Fractures and dislocations around a joint: immobilize the bone above and the bone below.
      3. Check pulse/capillary refill and movement/sensation BEFORE and AFTER splinting.
      4. In general, splint it as it lies; under axial traction, a long bone may be gently straightened, if there’s no great amount of pain or resistance.
      5. Thigh fractures should wait for a traction splint, if other injuries allow. If not, wrap or tape to other leg.
      6. Keep checking circulation to make sure the swelling hasn’t made the splint too tight.
      7. Dislocations: principle is to attempt reduction in the backcountry (beyond scope of this session)
      8. Open fractures: irrigate with high-pressure clean water (caution about contaminating self) and give antibiotic if have one.
   b. (Improvised splinting will be practiced later.)

6. BACK
   a. use a log roll (demonstrate) to roll the patient as a unit if you suspect a spinal injury, but check the back for wounds, bruises, deformity.

CONCLUSION: Review important points, using student outline
STEP ZERO: ASSESS AND MANAGE HAZARDS.
The patient AND you. ("A dead rescuer never did anyone any good.")

STEP 1: PRIMARY SURVEY.

STEP A: AIRWAY.

STEP A-1: CHECK FOR AIR MOVEMENT.

STEP A-2: OPEN AIRWAY. (BUT CAREFUL FOR BROKEN NECK!)

STEP B: BREATHING.

STEP B-1: ARTIFICIAL RESPIRATION.

STEP B-2: PLUG SUCKING CHEST WOUND.

STEP B-3: SPLINT MAJOR FLAIL CHEST.

STEP C: CIRCULATION.

STEP C-1: CARDIAC RESUSCITATION.

STEP C-2: CONTROL SEVERE BLEEDING.

STEP C-3: DETECT AND TREAT SEVERE SHOCK.

STEP 2: MANAGE.
("Don't just do something, stand there!")

STEP 3: FOCUSED H & P:
Ask, Look, Listen, Feel

VITAL SIGNS

HEAD/NEUROLOGICAL EXAMINATION

NECK

CHEST

ABDOMEN AND PELVIS

EXTREMITIES

- "Immobilize the joint above and below the broken bone, or the bone above and below the broken joint."
- "Check circulation and innervation BEFORE and AFTER splinting."
- "Splint it as it lies." (but straightening a fracture or cervical spine may be OK)
- "Use a traction splint on thigh fractures if you can."
- "Keep an eye out for swelling cutting off circulation."
- Reduce dislocations; irrigate open fractures, treat with antibiotics

BACK
